

How to implement aggregation switch stacking

Overview

This is generally implemented using 2 or more links between two logical devices. Using standards such as LACP, the two links are combined into a single logical link, with traffic. Switch stacking emerged in the late 1990s and early 2000s as a solution to simplify the management of multiple network switches. By linking switches together into a “stack,” administrators could manage them as a single entity and provide a single CLI interface, reducing complexity in configuration. Two common methods used to enhance switch deployments are: 1□ Switch Stacking - Treats multiple physical switches as one logical switch for easier management. 2□ Link Aggregation (LAG) - Combines multiple physical connections into one logical link to increase bandwidth and redundancy. UniFi gear doesn't support that yet. In addition, core switches are configured with the native AC function to manage APs and transmit wireless service traffic on the entire.
