Desirable: The interface will actively ask the other side to become an EtherChannel. 2. Auto: The interface will wait passively for the other side to ask to become an EtherChannel. Here's a quick overview with the two PAgP configuration opt. LACP is similar to PAgP but uses different terminology: 1. Active: The interface will actively ask the other side to become an EtherChannel. 2. Passive: The interface waits passively for the other side to ask to become an EtherChannel. At least one switch should use active mode. When both switches use passive mode, nothing will happen. I'll use the. Instead of PAgP or LACP, we can also manually enable the Etherchannel. I'll use the same topology to demonstrate this: Here's the configuration: That's all there is to it. Let's try our show commands. We'll start with an overview: In the output above, you can see we don't use any protocol. Let's take a closer look at the Port-channel interface: And. The last thing I want to show you about EtherChannel is load-balancing. Take a look at the following output: Use the show etherchannel load-balance command to see what the default configuration is. As you can see, this switch load balances based on the source MAC address. If you want, you can change this behavior with the port-channel load-balance.
