

Relay protection secondary grounding

Overview

Secondary equipment grounding refers to connecting the secondary equipment (such as relay protection and computer monitoring systems) in power plants and substations to the earth via dedicated conductors. Simply put, it establishes an equipotential bonding network, which is then connected to the. Ungrounded: There is no intentional ground applied to the system-however it's grounded through natural capacitance. Reactance Grounded: Total system capacitance is cancelled by equal inductance. This decreases the current at the fault and limits voltage across the arc at the fault to decrease. Current transformer (CT) secondary grounding is essential for safety, relay accuracy, and avoiding equipment damage. This article explains why CT secondary is grounded, how CT earthing works, and why CT secondary is shorted and grounded at only one point as per IEEE and ANSI standards.
