Overview

Wavelength division multiplexing (WDM) is a technology that combines two or more optical carrier signals of different wavelengths (carrying various information) at the transmitting end through a multiplexer (also called a combiner, Multiplexer) and couples them to the same optical fiber. Wavelength division multiplexing (WDM) is a technology that combines two or more optical carrier signals of different wavelengths (carrying various information) at the transmitting end through a multiplexer (also called a combiner, Multiplexer) and couples them to the same optical fiber. In fiber-optic communications, wavelength-division multiplexing (WDM) is a technology which multiplexes a number of optical carrier signals onto a single optical fiber by using different wavelengths (i. This technique enables bidirectional communications over a. Wavelength Division Multiplexing (WDM) is a technique in fiber-optic communication systems that enables multiple optical signals with different wavelengths to be combined, transmitted, and separated over a single optical fiber. This allows multiple channels of data to be transmitted simultaneously. WDM technologies allow organizations to place equipment at either end of a fiber pair and combine multiple wavelength channels on a single fiber pair instead of using multiple separate fibers pairs for every separate service. WDM allows communication in both the directions in the fiber cable. In WDM, the optical signals from different. Functionality: Fiber optic splitters, also known as beam splitters, operate by dividing an incoming optical signal into multiple output signals of equal or varying intensities. Components: They typically utilize passive optical components such as fused biconical taper (FBT) or planar lightwave.
